CONTENTS

- 1. Motivation**
- 2. Experimental program description**
- 3. The strengthening strategy**
- 4. Results**
- 5. Conclusions**

1. Motivation

- Large number of PRCLWP buildings across the country
- Interventions on them become more and more necessary after 50 years of existence
- Determine the seismic performance of the PRCWP
- Investigate the weakening induced by cut-outs in walls due to various reasons
- Analyse various strengthening systems for initial load bearing capacity restoration of the elements
- Evaluate the material and labour costs for each strengthening system since few literature is known on this aspect

2. Experimental program description

TEST SET-UP

-  CUT-OUT OPENING
-  SIMPLY SUPPORTED EDGE
-  FIXED EDGE
-  WALL PANEL
-  WING ELEMENT
- $\pm V$ LATERAL LOAD
- N AXIAL LOAD

Length units: mm

3. The strengthening strategy

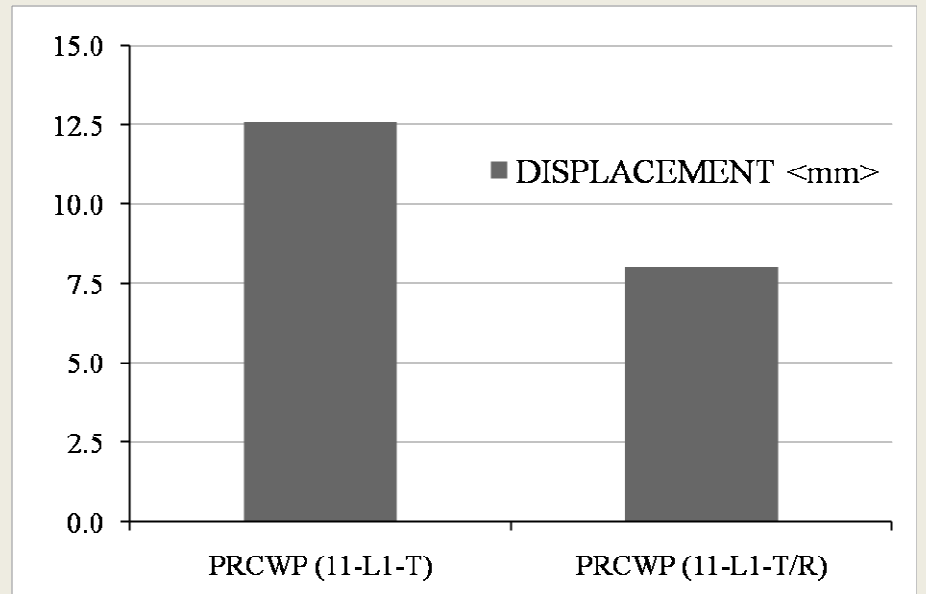

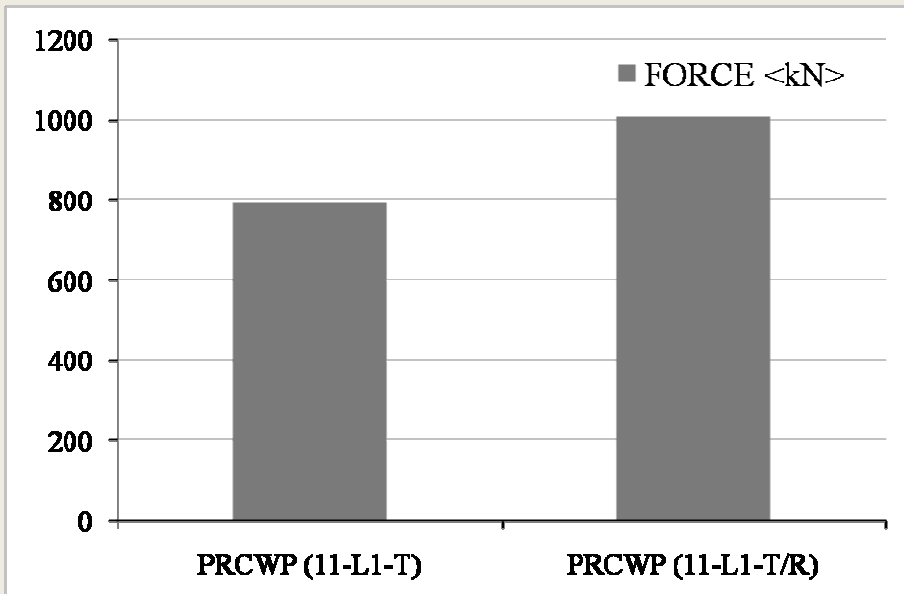

4. Results

5. Conclusions

- In terms of maximum load supported by the element the PRCWP (11-L1-T) recorded 793.5 kN , while PRCWP (11-L1-T/R) 1007.5 kN.
- Drift level corresponding to the maximum load was 12.59 mm for the unstrengthened wall while for the post-damage strengthened one 8.02 mm.
- The PRCWP (11-L1-T/R) could not be taken to failure due to the available capacity of the testing facility, but analyzing the data one can remark that at a displacement level of 8.02 mm we have an increase in load bearing capacity of 60%.
- The strengthening system using TRM with CF grid proved to be the most expensive in the current experimental program (276.42 EUR/m²), but we have to take into consideration the fact that the crack injection was not performed in the other cases and also the idea of strengthening versus retrofitting implying the carbon fiber grid wraps raised the total price.

Thank you for your kind attention!
